Part 3: Time Complexity Basics

Constant, Linear, and Quadratic Time

Notes for CSC 100 - The Beauty and Joy of Computing
The University of North Carolina at Greensboro

Reminders

Readings:

Emma - contribute to on-line discussion by Monday!

Homework:

Homework 2 due on Wednesday

On the horizon: Midterm on Wednesday, Oct. 4

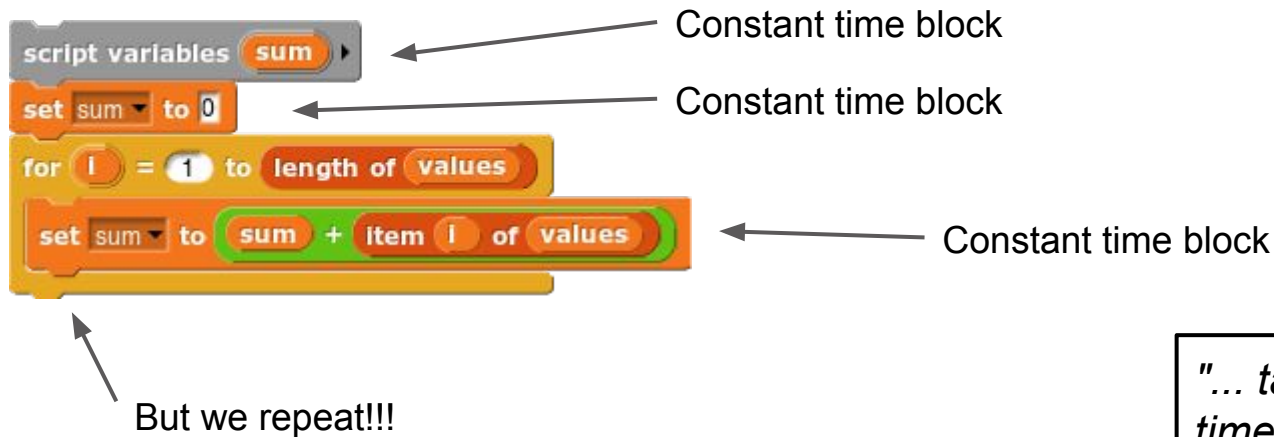

Constant time

We say a script (or part of a script or block definition) takes *constant time* if it is a constant (usually small) number of basic steps, regardless of input.

Question: Are all of these constant time?

What about loops?

The number repetitions depends on length of "values"

- So this is not constant time...

"... takes constant time if it is a constant (usually small) number of basic steps, regardless of input"

Constant time operations, repeated "length of input" times is linear time

Mathematically: Constant time loop body is time "c"

Repeated "n" times where n is length of list

Total time is then $c \cdot n$ (that's a linear function!)

General iterator pattern

On previous slide:

- Time was expressed as a function of input size
- Could write time as $T(n) = c*n$

Very important
"Big Idea"!!!

In general:

Mystery operation!!!

We know how many times it repeats, and all basic blocks are constant time except perhaps our "do something..." block

- In general, if time for "do something..." block is $T(n)$, then time for complete script with loop is $n*T(n)$
- If "do something" is constant time, total time is $c*n$ (linear)
- If "do something" is linear time, total time is $c*n^2$ (quadratic)

Two challenges

What's the time complexity?

```
+ max + pos + in + pList : +
script variables maxPos ▶
set maxPos to 1
for i = 2 to length of pList
  if item i of pList > item maxPos of pList
    set maxPos to i
report maxPos
```

The code block consists of the following blocks: a title block '+ max + pos + in + pList : +', a 'script variables' block for 'maxPos', a 'set maxPos to 1' block, a 'for i = 2 to length of pList' loop block, an 'if item i of pList > item maxPos of pList' conditional block with a 'set maxPos to i' block inside it, and a 'report maxPos' block at the end.

What's the time complexity?

```
+ sort + pList : +
script variables maxPos ▶
for i = length of pList to 2
  set maxPos to max pos in first i of pList
  swap i and maxPos of pList
```

The code block consists of the following blocks: a title block '+ sort + pList : +', a 'script variables' block for 'maxPos', a 'for i = length of pList to 2' loop block, a 'set maxPos to max pos in first i of pList' block inside the loop, and a 'swap i and maxPos of pList' block inside the loop.

Plotting the Running Times

Measured (using Snap!) and calculated running times for max pos:

Note: The straight line of this graph should remind you of linear function graphs from math class!

Plotting the Running Times

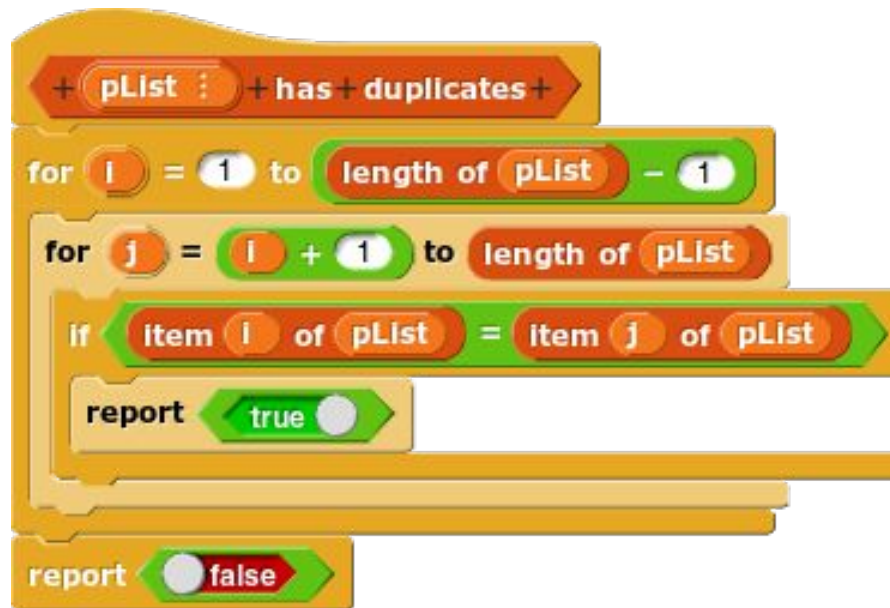

Measured (using Snap!) and calculated running times for sort:

Note: The nice smooth parabola should be familiar to you from math class!

Another challenge

The following predicate tests whether a list has any duplicates:

Question: What's the time complexity?

Predicting Program Times - Linear

Basic idea: Given time complexity and sample time(s) can estimate time on larger inputs

Linear time: When input size doubles, time doubles

When input size triples, time triples

When input size goes up by a factor of 10, so does time

Example: A linear time algorithm runs in 10 sec on input size 10,000
How long to run on input size 1,000,000?

Answer: $1,000,000 / 10,000 = 100$ times larger input

Therefore 100 times larger time, or $10 * 100 = 1,000$ sec

Or $1,000 / 60 = 16.667$ minutes

Predicting Program Times - Quadratic

Basic idea: Given time complexity and sample time(s) can estimate time on larger inputs

Quadratic time: When input size doubles (2x), time quadruples (4x)

Input size goes up by a factor of 10, time goes up $10^2=100$ times

Input size goes up k times, time goes up k^2 times

Example: A quadratic time algorithm runs in 10 sec on input size 10,000

How long to run on input size 1,000,000?

Answer: $1,000,000 / 10,000 = 100$ times larger input

Therefore $100^2 = 10,000$ times larger time, or 100,000 sec

Or $100,000 / 60 = 1666.7$ minutes (or 27.8 hours)

Predicting Program Times - Your Turn

Joe and Mary have created programs to analyze crime statistics, where the input is some data on each resident of a town

- Joe's algorithm is quadratic time
- Mary's algorithm is linear time
- Both algorithms take about 1 minute for a town of size 1000

Both would like to sell their program to the City of Greensboro (population 275,000)

Problem: Estimate how long each program would take to run for Greensboro

Summary

- Algorithm "time complexity" is in basic steps
 - Common complexities from this lecture, from fastest to slowest are constant, linear, and quadratic
 - A single step, or sequence of constant-time blocks is constant time
 - A simple loop with constant time operations repeated is linear time
 - A loop containing a linear time loop is quadratic
 - Speed depends on algorithm time complexity
 - Constant time is great, but not many interesting things are constant time
 - Linear time is very good
 - Quadratic time is OK
 - Given time complexity and one actual time, can estimate time for larger inputs
-
