Goal: Protect both Confidentiality and Integrity

Some techniques that have been used:
- Encrypt with hash of message: \( E(K, M \ || \ H(M)) \)
  - \( E \) better be non-malleable!! (problem with WEP using RC4)
- Encrypt with MAC: \( E(K_1, M \ || \ MAC(K_2, M)) \)
  - Used in SSL/TLS
- Encrypt followed by MAC: \( C = E(K_1, M) \ ; \ T = MAC(K_2, C) \)
  - Used in IPSec
- Encrypt and MAC: \( C = E(K_1, M) \ ; \ T = MAC(K_2, M) \)
  - Used in SSH

Notes:
- Important to use different keys for encryption and MAC (avoid interactions)
- All techniques have drawbacks

New and Improved! Authenticated Encryption

High-Level Idea

Ideas:
- Design for confidentiality and integrity together - use a single key!
- Allow some data to be transmitted in the clear, but still authenticated
JCA - Using Authenticated Encryption
Example using GCM (one AE mode)

```
GCMParameterSpec s = ...;
cipher.init(..., s);
// If the GCM parameters were generated by the provider, it can
// be retrieved by:
// cipher.getParameters().getParameterSpec(GCMParameterSpec.class);
cipher.updateAAD(...);  // AAD (optional - must be before plaintext)
cipher.update(...);     // Multi-part update
cipher.doFinal(...);    // conclusion of operation

// Use a different IV value for every encryption
byte[] newIv = ...;
s = new GCMParameterSpec(s.getTlen(), newIv);
cipher.init(..., s);
```

On encryption: Tag is embedded in output ciphertext (you don’t have to handle!)
On decryption: Bad tag results in throwing AEADBadTagException

Two AE modes: CCM and GCM

**CCM (Counter with CBC-MAC)**
- Ciphertext produced using CTR mode
- MAC produced using CBC-based MAC
- The good: Strong, provable security under certain assumptions
- The bad:
  - Encrypt/MAC require two independent block cipher calls
  - Inclusion of CBC means not parallelizable

**GCM (Galois/Counter Mode)**
- CTR mode encryption - almost... incr 32-bits -> $2^{39}$-bit limit on size
- GHASH to auth ciphertext - one Galois Field (GF) mult per block
- The good:
  - Strong, provable security under certain assumptions
  - Per block: 1 block cipher call, and one GF mult (Intel instruction) - fast!
  - Block cipher calls are parallelizable (just like CTR mode)
- The bad: ?

GCM - Algorithm Overview

Hash and Encryption Functions

![Diagram of GCM Authentication and Encryption Functions]

A little misleading. When combined, these X’s are ciphertext blocks (called Y’s below)!
GCM - Algorithm Overview

Key Wrapping

Consider: In the JCA KeyStore, keys are stored in a file. How are they protected?

- Password used to “unlock” the KeyStore
- Need to use encryption with one key to encrypt another key
- An AES 256-bit key spans multiple blocks of AES
- Can a specially designed mode help?
  - Advantage: Limited size plaintext (can have all in memory at once)
  - Speed isn’t as big an issue as it is with bulk encryption
  - Wrapped key is random - how do you know decryption is right - authentication!
  - Specially designed mode: Key Wrap (KW) mode

Related notions with different terminology:

- Key Wrapping: Encrypting a symmetric key using symmetric cipher
- Key Encapsulation: Encrypting a symmetric key using a public key algorithm (e.g., for hybrid encryption)

AES Key Wrap Mode

Pseudocode from NIST publication
PRNGs from Hash Functions and MACs

Observations:
- PRNGs need uniformly distributed output
  - Good hash functions and MACs have uniformly distributed outputs
- PRNGs need to be one-way so seed/state can’t be derived
  - Good hash functions and MACs are preimage resistant (one-way)
- PRNGs need output to be computationally uncorrelated (independent)
  - Good hash functions and MACs have collision resistance

And in addition: Hash functions and MACs tend to be fast

So…. Can we use hash functions and MACs to make good PRNGs?

PRNGs from hash functions

Idea: Concatenate seed and counter, and run through hash fn

So: Initialize $V = \text{seed} \oplus 0$

This is essentially how the standard Java SHA1PRNG instance of SecureRandom works (generally the default)
PRNGs from MACs

Can use a simple feedback loop with a MAC (NIST SP 800-90)

Some other options
- Can use a MAC with a counter, like previous slide (IEEE 802.11i does this)
- Can do feedback, but concatenate a constant (the seed) each iteration (TLS)
